

AI Music Recommendation System

Training a hybrid recommendation model from playlists, song features, and user feedback.

Main Model

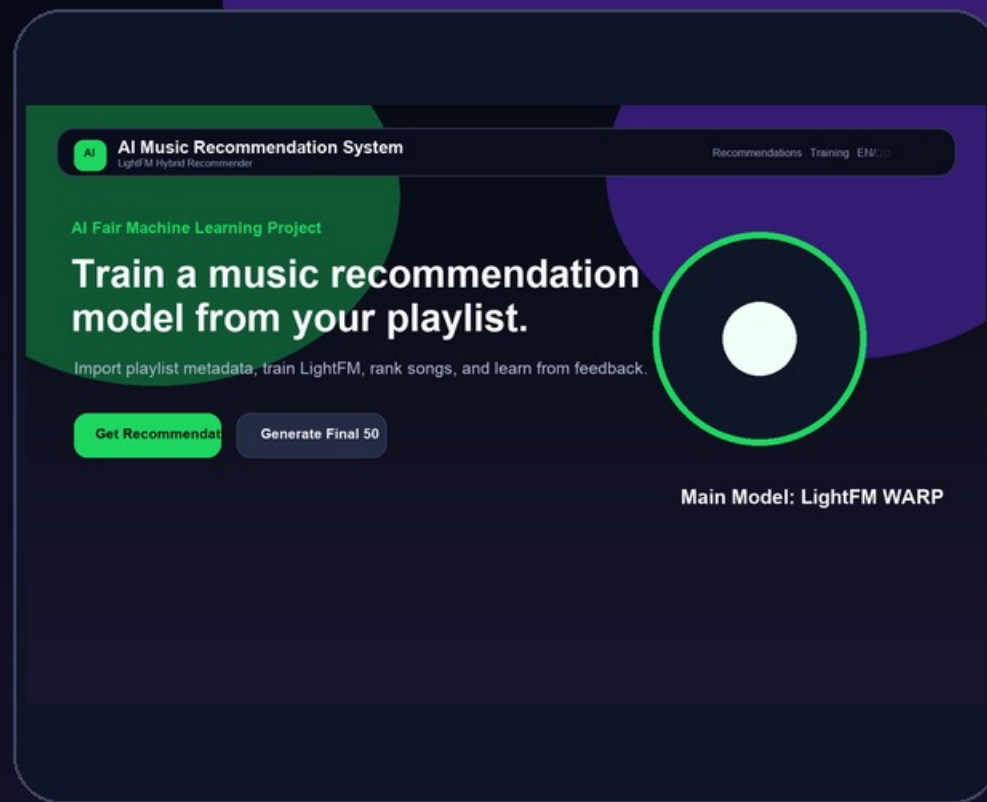

LightFM

Output

Daily 50

Storage

CSV

Presenter: AI Fair Project Team

The project solves a real music recommendation problem.

It learns from playlist behavior and feedback instead of returning random songs.

Problem

Music libraries are too large to browse manually. A recommender should learn the listener's taste.

Users

Students, music listeners, and AI Fair visitors who want to see a model learn from data.

Goal

Show the complete machine learning loop: data, features, training, prediction, and feedback.

Thesis: this is not just a search page. It creates training data, trains a hybrid model, and updates recommendations after feedback.

A local Flask app turns music metadata and user actions into training data.

All data is stored locally. Online services are used only for public song metadata. The system does not download music audio.

The dataset is inspectable, structured, and ready for machine learning.

songs.csv

Song metadata + audio features track, artist, genre, energy, tempo, popularity

interactions.csv

Training signals

playlist_import, manual_add, like, dislike

feedback.csv

Explicit feedback

Like = 1, Dislike = 0

playlists.csv

Import history

source, song_count, created_at

QQ Music links are parsed safely, then metadata is imported.

- Supports playlist/{id}, taoge.html?id=, disstid=, tid=, and pure numeric IDs.
- Tries multiple metadata endpoints: qzone, v8 playlist, and musicu.fcgi.
- Imports metadata only. It does not download music or bypass copyright.
- If QQ fails, the user can use manual input or song search.

URL extraction example

QQ playlist URL

- > extract playlist_id
- > fetch metadata
- > normalize songs
- > save songs.csv
- > create interactions

The app searches local data first, then public music metadata APIs.

1

Local CSV

Fast, stable, includes model-ready features.

2

Deezer

Public metadata for mainstream songs.

3

MusicBrainz

Open music database, rate limited safely.

4

Last.fm

Optional API key. Skipped if missing.

Every request uses `timeout=8` and `try/except`, so API failure does not crash the Flask app.

Songs become item feature tokens that LightFM can learn from.

genre:pop

artist:the_weeknd

tag:dance

source:qq

energy:high

tempo:fast

valence:positive

danceability:high

popularity:high

The model learns from interpretable features such as high energy, fast tempo, genre, artist, source, and mood.

Playlist actions and feedback become a user-song interaction matrix.

playlist_import

+1.0

manual_add

+1.0

like

+2.0

dislike

-1.0

LightFM WARP trains from positive ranking examples. Dislikes are stored and used during re-ranking to lower scores.

LightFM is the main machine learning model because it supports hybrid recommendation.

- Open-source recommender library.
- Learns from implicit and explicit feedback.
- Uses WARP ranking loss for Top-N recommendation.
- Combines interactions with item features.
- Works well for a school AI Fair dataset.

Training object

```
model = LightFM(loss="warp")  
model.fit(interactions,  
item_features,  
sample_weight,  
epochs=30)
```

The UI exposes the machine learning pipeline.

- Import or manually add songs.
- Write interactions.csv rows.
- Build item feature tokens.
- Train LightFM WARP.
- Save lightfm_model.pkl.
- Show model status in the UI.

Final recommendations blend learned preference and content similarity.

$$\text{final_score} = 0.7 \times \text{model_score} + 0.3 \times \text{content_similarity_score}$$

model_score

The trained LightFM model predicts how much the user may like each candidate song.

content_similarity

Cosine similarity compares audio features such as energy, tempo, danceability, and mood.

rule explanation

Reasons are generated deterministically, not by a language model.

The app looks and feels like a modern music recommendation dashboard.

Bilingual UI, playlist import, manual songs, model status, recommendation cards, Like/Dislike, and Daily 50 output.

The system produces ranked songs, explanations, and a final 50-song daily mix.

The screenshot displays the 'AI Music Recommendation System' interface. At the top, it says 'LightFM Hybrid Recommender' and has tabs for 'Recommendations', 'Training', and 'ENCODE'. The main section is titled 'Recommendations' with the subtitle 'Ranked by learned model score plus content similarity.' Below this, there are six song recommendation cards arranged in a 2x3 grid. Each card shows the song title, artist, genre, and three scores: Model, Content, and Final. A reason for the recommendation is provided at the bottom of each card.

Song	Artist	Genre	Model	Content	Final	Reason
Shape of You	Ed Sheeran	Pop	0.92	0.76	0.86	shares genre, tempo, and energy profile.
Blinding Lights	The Weeknd	Pop	0.90	0.73	0.83	shares genre, tempo, and energy profile.
Believer	Imagine Dragons	Rock	0.87	0.70	0.81	shares genre, tempo, and energy profile.
Titanium	David Guetta ft. Sia	Electronic	0.84	0.67	0.78	shares genre, tempo, and energy profile.
Lose Yourself	Eminem	Hip-hop	0.82	0.64	0.76	shares genre, tempo, and energy profile.
Levitating	Dua Lipa	Pop	0.80	0.61	0.73	shares genre, tempo, and energy profile.

Top Cards

10

Final Mix

50

Explanation

Rules

Feedback

Retrain

After Like/Dislike feedback, interactions.csv changes, the model retrains, and future rankings shift.

Daily Recommendation Mix turns model scores into a show-ready playlist.

AI Music Recommendation System
LightFM Hybrid Recommender

Recommendations Training EM

Daily Recommendation Mix

Final 50-song output for the AI Fair demo.

1	Shape of You	Ed Sheeran · Pop	0.910
2	Blinding Lights	The Weeknd · Pop	0.900
3	Believer	Imagine Dragons · Rock	0.890
4	Titanium	David Guetta ft. Sia · Electronic	0.880
5	Lose Yourself	Eminem · Hip-hop	0.870
6	Levitating	Dua Lipa · Pop	0.860
7	Riptide	Vance Joy · Indie	0.850
8	Earned It	The Weeknd · R&B	0.840
9	Shape of You	Ed Sheeran · Pop	0.830
10	Blinding Lights	The Weeknd · Pop	0.820
11	Believer	Imagine Dragons · Rock	0.810
12	Titanium	David Guetta ft. Sia · Electronic	0.800
13	Lose Yourself	Eminem · Hip-hop	0.790
14	Levitating	Dua Lipa · Pop	0.780
15	Riptide	Vance Joy · Indie	0.770
16	Earned It	The Weeknd · R&B	0.760
17	Shape of You	Ed Sheeran · Pop	0.750
18	Blinding Lights	The Weeknd · Pop	0.740

- Generates up to 50 songs.
- Filters songs already used for training.
- Reduces repeated artists and genres.
- Can be copied as playlist text output.

The same pipeline can support personal and school music discovery.

For students

Learn ML from a product everyone understands: playlists and song recommendations.

For music apps

Convert playlist behavior and feedback into a recommendation loop.

Future work

Add richer audio analysis, multi-user data, metrics, and stronger diversity controls.

Most useful improvement: collect more feedback over time and evaluate precision@k and recall@k .

The project uses AI help responsibly and avoids copyright risks.

- AI assistance was used for coding, debugging, UI writing, and documentation support.
- The model and code were checked and understood by the student.
- No local LLM, LM Studio, Ollama, or OpenAI API is used for explanations.
- QQ import uses metadata only, with no audio download or unauthorized playback.

Risk controls

Timeouts for API requests, friendly error fallback, local CSV storage, rule-based explanations, and no private audio scraping.

LIMITATIONS

The model is real, but dataset size and public metadata sources limit accuracy.

Small dataset

A single demo user is useful for demonstration, not production-scale personalization.

Estimated features

Some online results do not provide true audio features, so the app estimates from metadata.

Unstable APIs

QQ Music public endpoints may change, so the app includes fallback and manual input.

Future improvements: real audio-feature sources, multi-user data, train/test evaluation, precision@k, recall@k, and stronger diversity re-ranking.

Quick start: open the app, import music taste data, then train the model.

- 1 Start the app**
Run python app.py and open the local URL.
- 2 Import or add songs**
Paste a QQ playlist link or type Song - Artist lines.
- 3 Check the dataset**
The app saves local CSV training data.
- 4 Train the model**
Click Train Model to build LightFM.

A live demo can show the full ML loop in under three minutes.

Step 1

Search or import

Use familiar songs or a QQ playlist.

Step 2

Create interactions

Add songs to the training playlist.

Step 3

Train LightFM

Show users, songs, interactions, and item features.

Step 4

Recommend

Show Top 10 scores and rule-based reasons.

Step 5

Feedback

Click Like or Dislike to update training data.

Step 6

Final 50

Generate a Daily Recommendation Mix.

Key line: every click creates data that can change the trained model.

If an online service fails, the system still works through local data and manual input.

If QQ import fails

Use manual playlist input or Search Songs. Public QQ endpoints can change or block some playlists.

If API search is slow

The app uses timeouts and skips failed providers so Flask stays running.

If LightFM is unavailable

The app falls back to content similarity and a logistic regression feedback model.

The project is designed for live demos: API errors become friendly messages while local data and the recommender still work.

CLOSING

This project shows the full ML loop: data, features, training, ranking, and feedback.

Playlist import creates implicit feedback. Like/Dislike creates explicit feedback. LightFM learns preferences and ranks songs the user is likely to enjoy.

Thank you. Questions?
